Selection for Quantitative Traits

polygenes and major genes

True situation

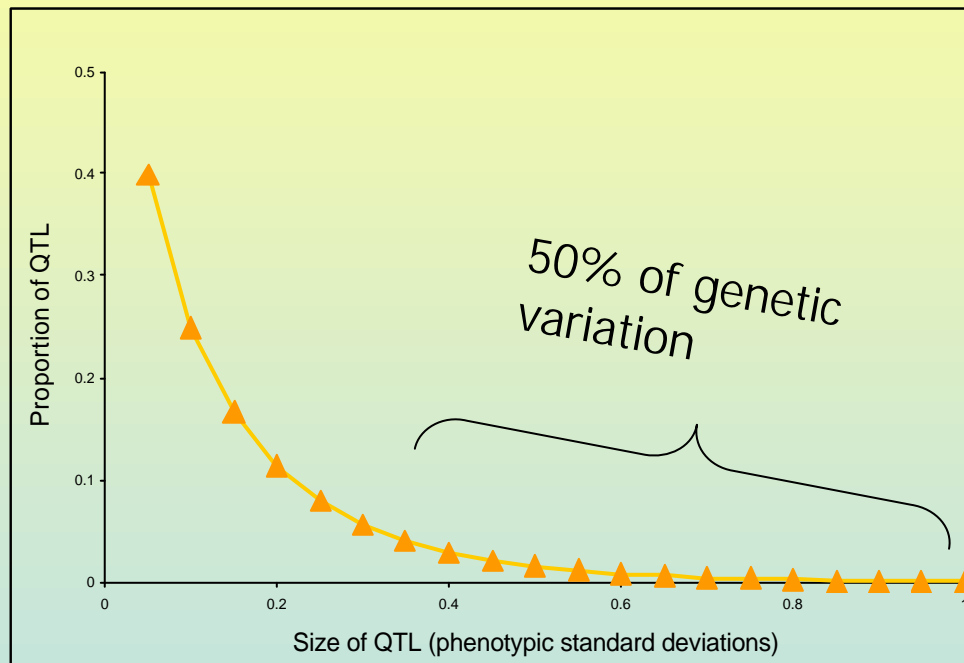

Genetic	Effects	
	Environment	Phenotype
+16	-10	+6
+5	+9	+14
-10	+20	+10

Observed situation

Phenotype
+6
+14
+10

How many genes?

- Maybe 5-10 large QTL explain the majority of the genetic variance.
- Mapping experiments should be able to detect these large QTL

Many small genes with small effect,
few with large effect

Marker Assisted Selection

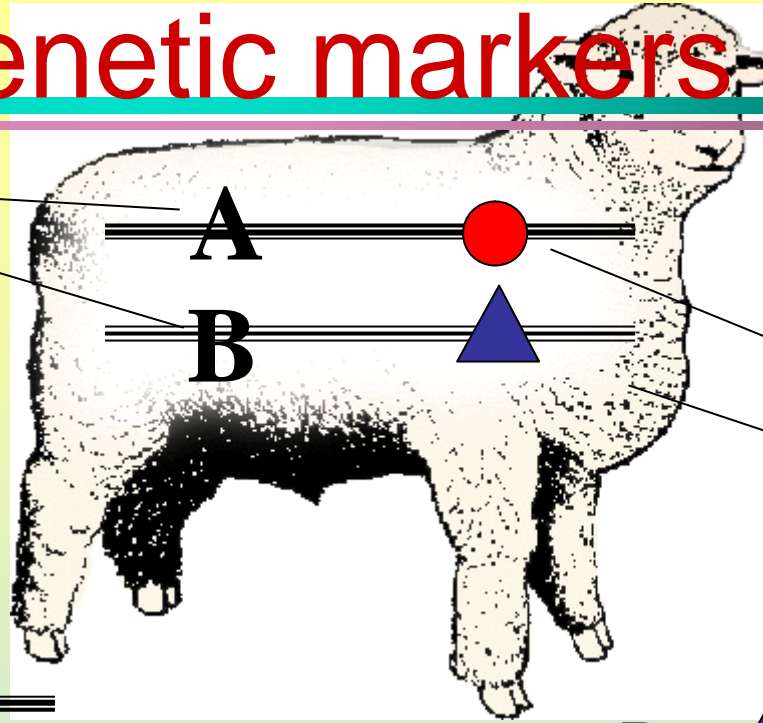

How it works

- Indirect markers
- Direct markers

Indirect genetic markers

Marker gene alleles

A Ram:

Major gene alleles

His semen:

Indirect genetic markers

Can select among offspring ...

'recombinants'

Indirect genetic markers

Phase can be opposite

'recombinants'

Direct genetic markers

We like to find
the actual
mutations!

A - always circle, always good

B - always triangle, always bad

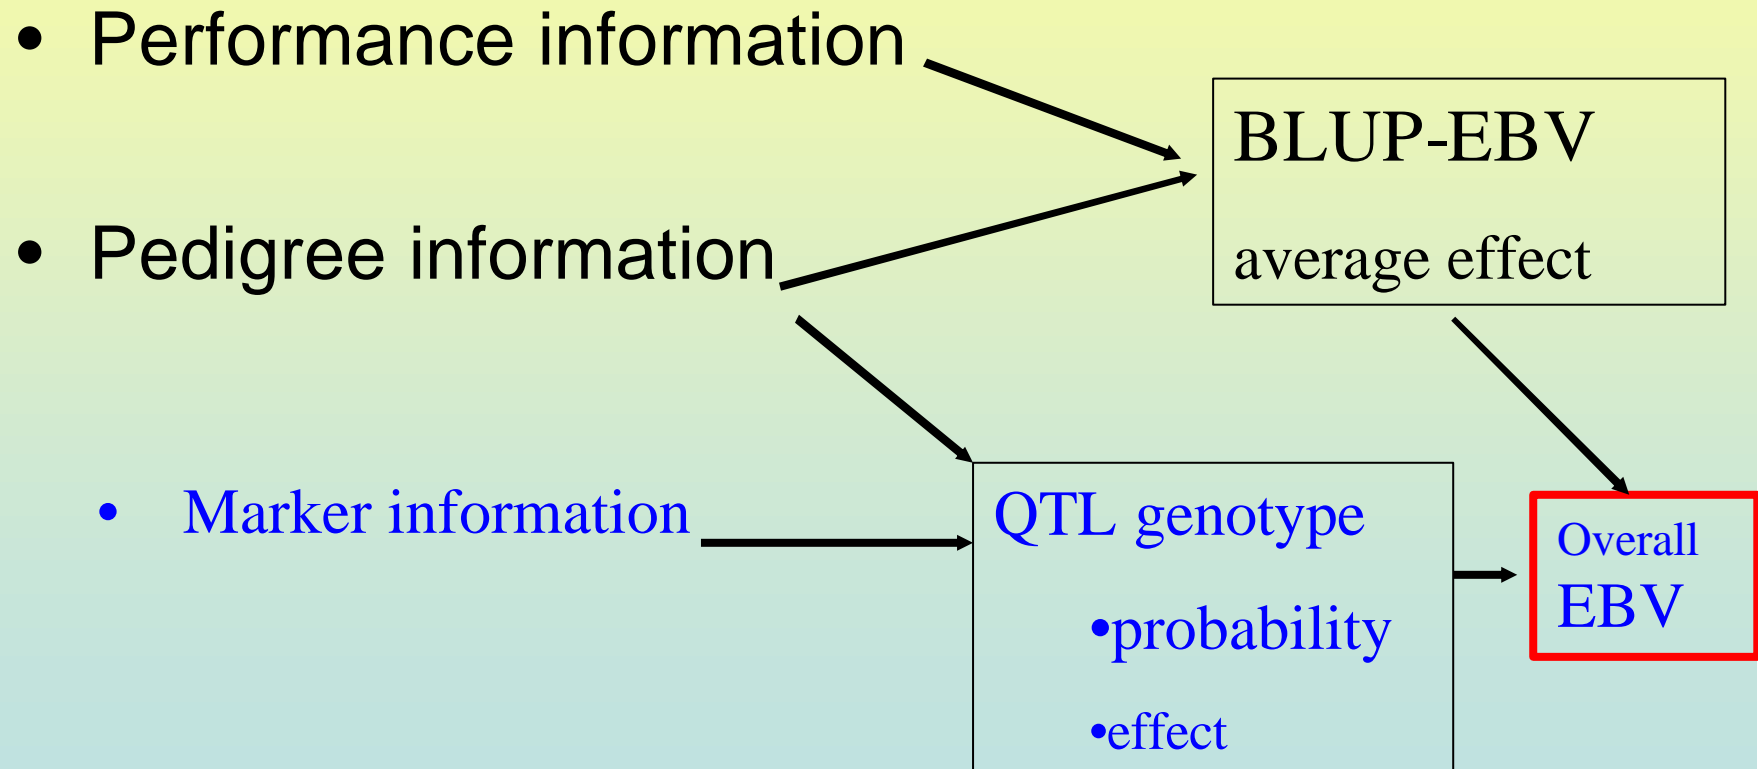

Selecting for QTL genotypes

- Increase desired allele frequency at QTL
- Introgressing them into lines
- In addition to polygenic selection

Normal Genetic Evaluation

- Performance information
 - Pedigree information
-
- ```
graph LR; A[Performance information] --> B[BLUP-EBV
average effect]; C[Pedigree information] --> B;
```
- BLUP-EBV  
average effect

# Genetic Evaluation with QTL

# Effect of MAS on rate of genetic gain

|                            | Selection <i>after</i> recording |       | Selection <i>before</i> recording |       |
|----------------------------|----------------------------------|-------|-----------------------------------|-------|
|                            | Gen 1                            | Gen 5 | Gen 1                             | Gen 5 |
| $h^2 = 0.11, V_{QTL}=0.33$ | +21%                             | +6%   | +45%                              | +23%  |

| $h^2 = 0.27, V_{QTL}=0.11$ | +1.3%                            | +1.3% | +8%                               | +6%   |

Meuwissen and Goddard, 1996

# Conditions that are good for Marker Assisted Selection

- Where heritability is low
  - e.g. fertility, nr. of lambs
- Where the trait is sex limited.
  - e.g. maternal effects, fertility, nr. of lambs
- Trait not measurable before first selection
  - e.g. longevity, micron blowout, fertility.
  - Most traits when using juvenile selection.
- Trait is difficult to measure.
  - e.g. disease resistance, recessive conditions, feed efficiency  
pigmented fibres, carcass traits

# Discussion on simulation studies

- They assume response in one trait
  - Need whole breeding objective context
  - More a matter of *shifting response between traits* rather than increasing overall response

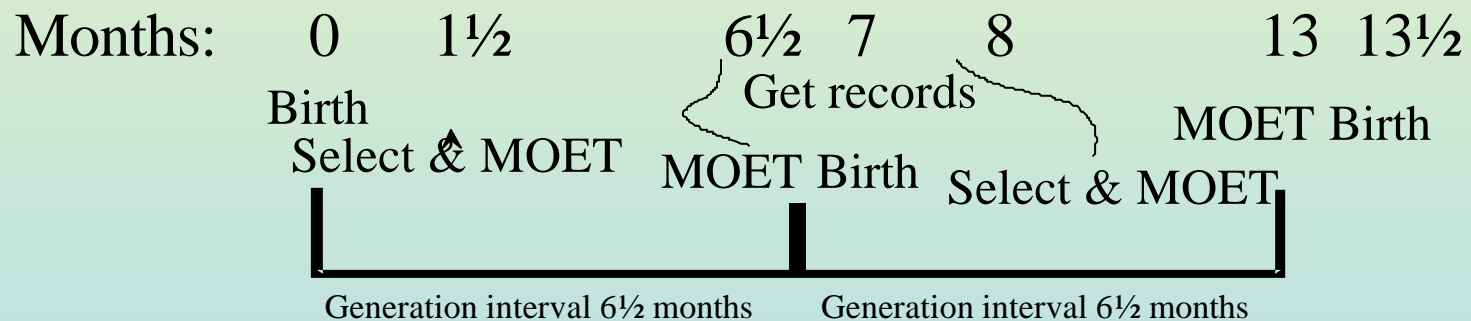

# Discussion on simulation studies

- They assume response in one trait
  - Need whole breeding objective context
  - More a matter of *shifting response between traits* rather than increasing overall response
- They assume abundant recording of pedigree and gene testing
  - Will we have cheap DNA testing available?
  - We can apply strategies to save on genotyping.
  - Some degree of phase-testing is needed
- They assume gene effects are known
  - Need monitoring by measurement

# Conclusion on MAS

- Effect on extra gain in breeding programs maybe limited to cases where
  - There are special genes with large effect
    - Disease resistance, Booroola, etc.
  - Breeding objective traits are difficult to measure
    - Carcass Traits, Feed Efficiency, Disease
  - When reproductive technologies are used

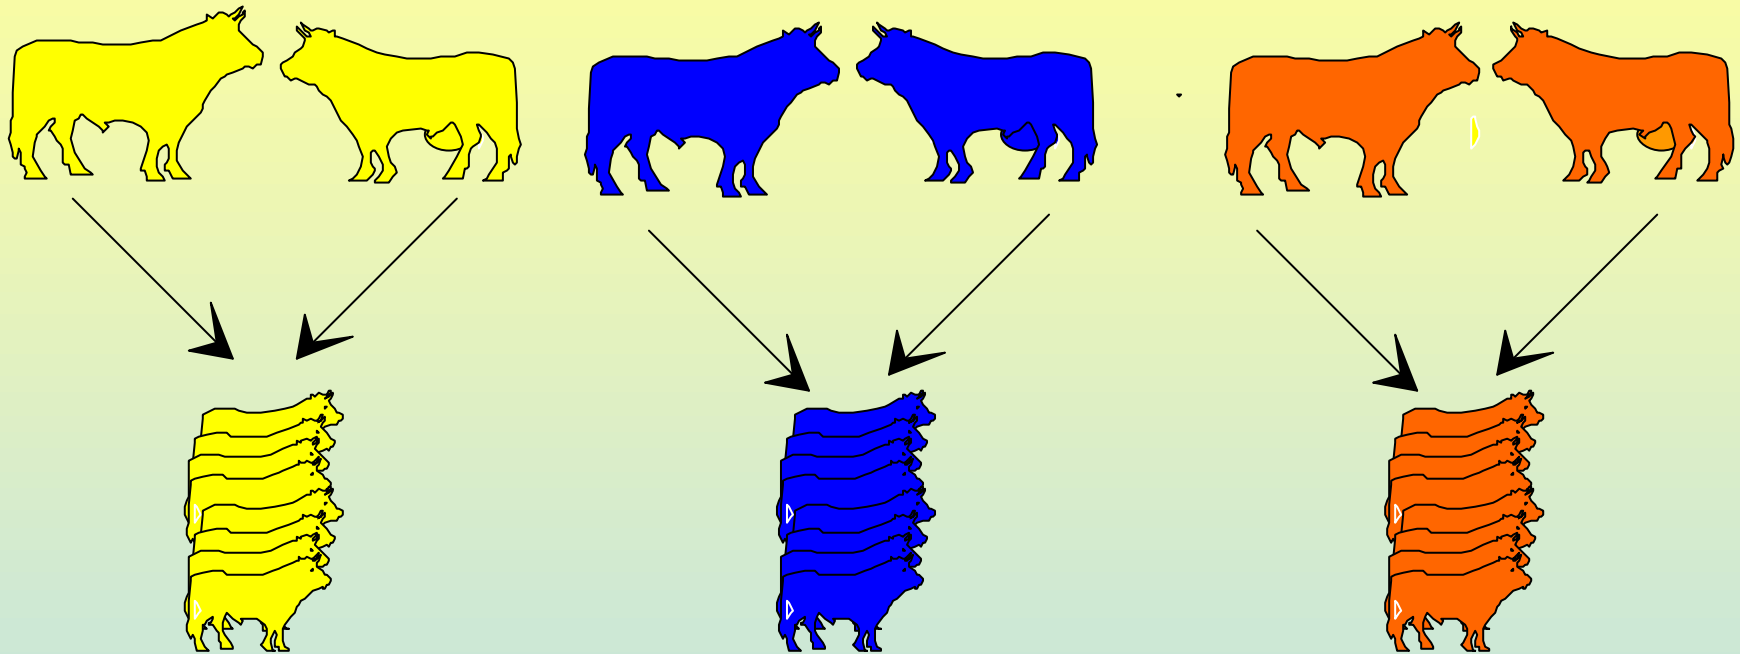

# Juvenile sheep MOET/JIVET

More offspring of top ewe *before* testing it

Select based on parent average

# Between versus within family selection

No own information (performance or genotype):

Selection based on parent average

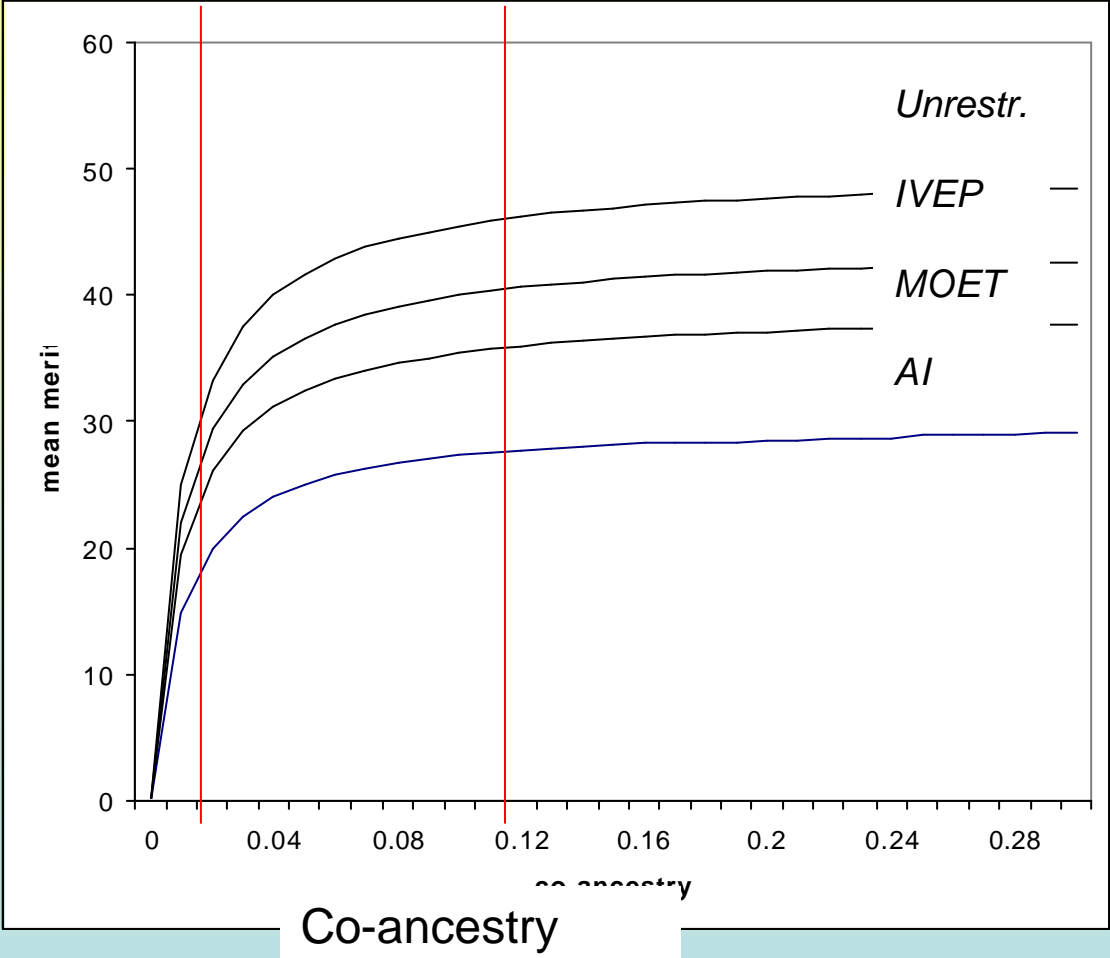

More between-family selection - ***more inbreeding***

# Genetic gain versus genetic diversity

- Sustainable breeding programs require optimal selection balancing genetic gain and genetic diversity
- Potential short term benefits from reproductive technologies are inhibited by the need to maintain diversity

# The balance between increased merit and inbreeding

Mean merit

# Between versus within family selection

Own information (performance or genotype):

More variation within families

More within-family selection – *less inbreeding*

# MAS combined with reproductive technologies

- Genotype testing provides within family information
- Exploiting this variation allows early selection and genetic gain without jeopardizing inbreeding

# Modelling Genotype Information in Beef Cattle Selection for RFI

**B.J. Wood<sup>1</sup>, J.H.J. van der Werf<sup>1</sup> and P.F.  
Parnell<sup>2</sup>.**

<sup>1</sup>Animal Science, UNE, Armidale NSW, 2351.

<sup>2</sup>NSW Agriculture Beef Industry Centre, UNE, Armidale NSW, 2351

# Australian Beef Breeding Objectives

- Growth
- Reproduction
- Feed Efficiency - RFI
- Carcass quality characteristics
  - MARBLE SCORE
  - TENDERNESS/PALATABILITY

# Australian Beef Breeding Objectives

- Growth
- Reproduction
- Feed Efficiency - RFI
- Carcass quality characteristics
  - MARBLE SCORE
  - TENDERNESS/PALATABILITY

# Residual Feed Intake (RFI)

Aim :

To model the change in response due to RFI  
QTL and model different selection strategies

- Residual feed intake – measure of the efficiency of an animal
- Heritable (0.39)
- Expensive to measure
  - 71 day feeding trial

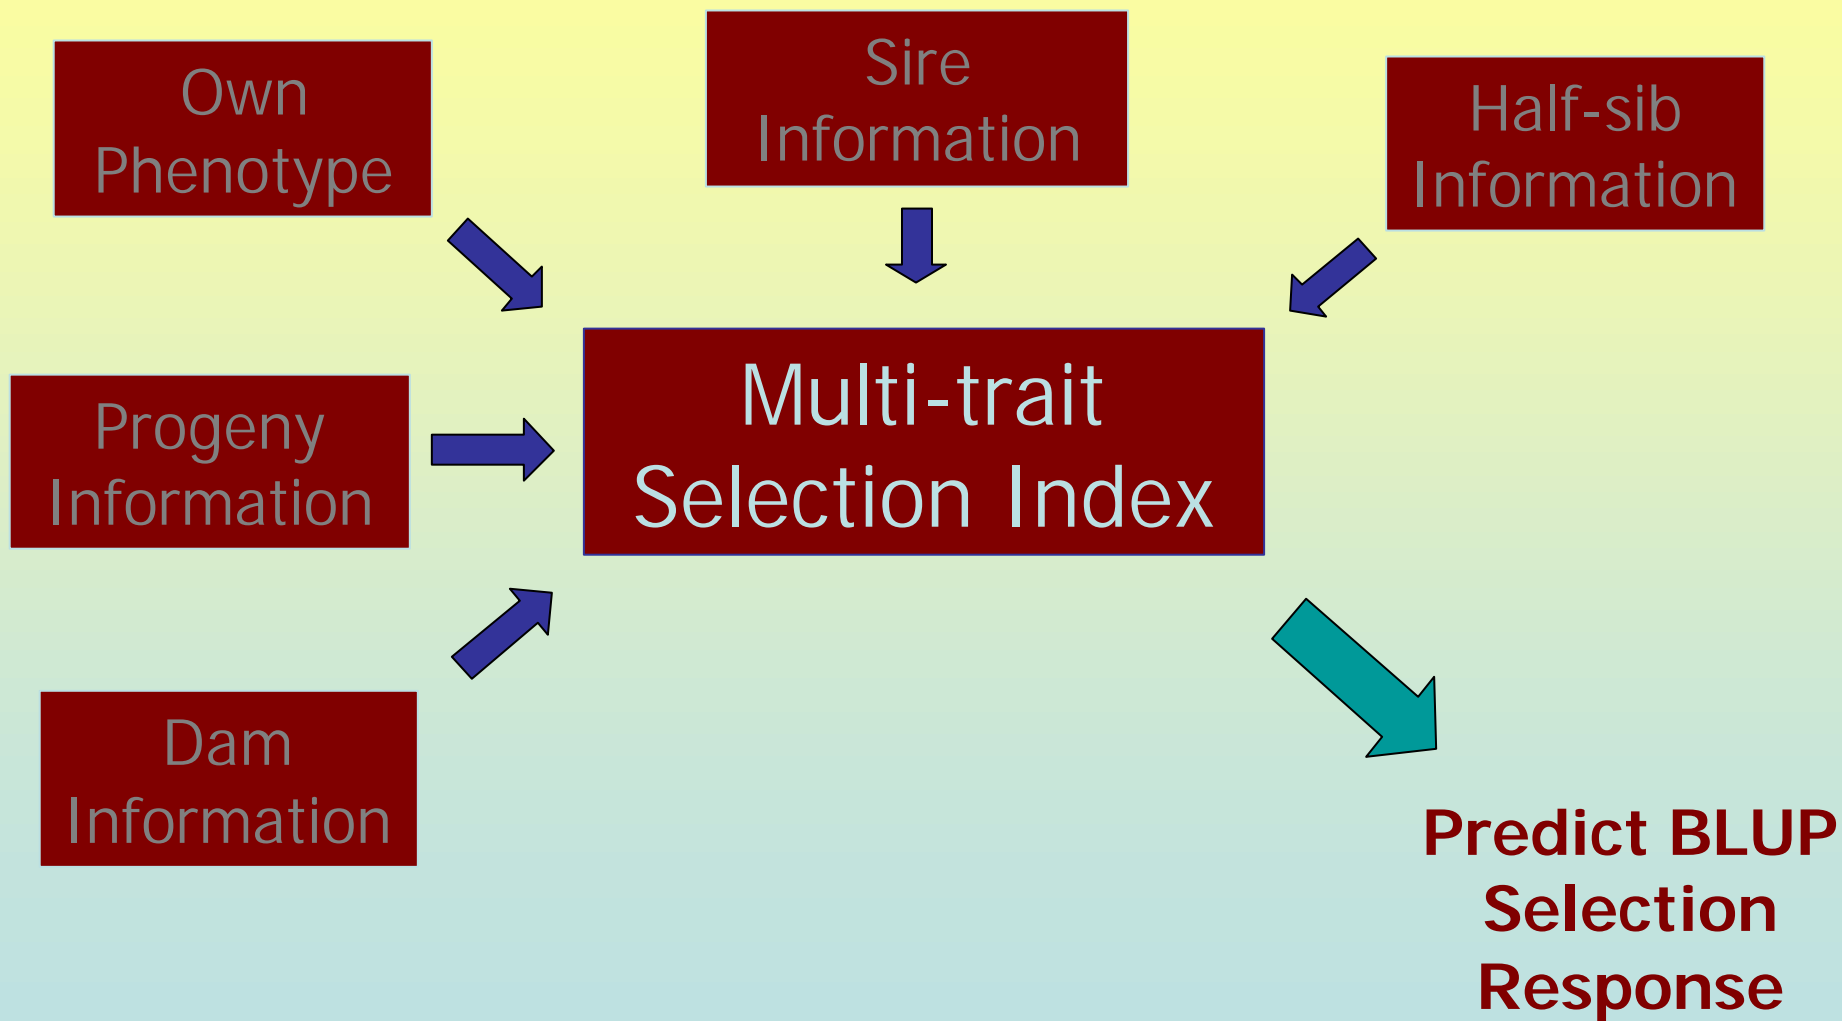

# Current Genetic Evaluation

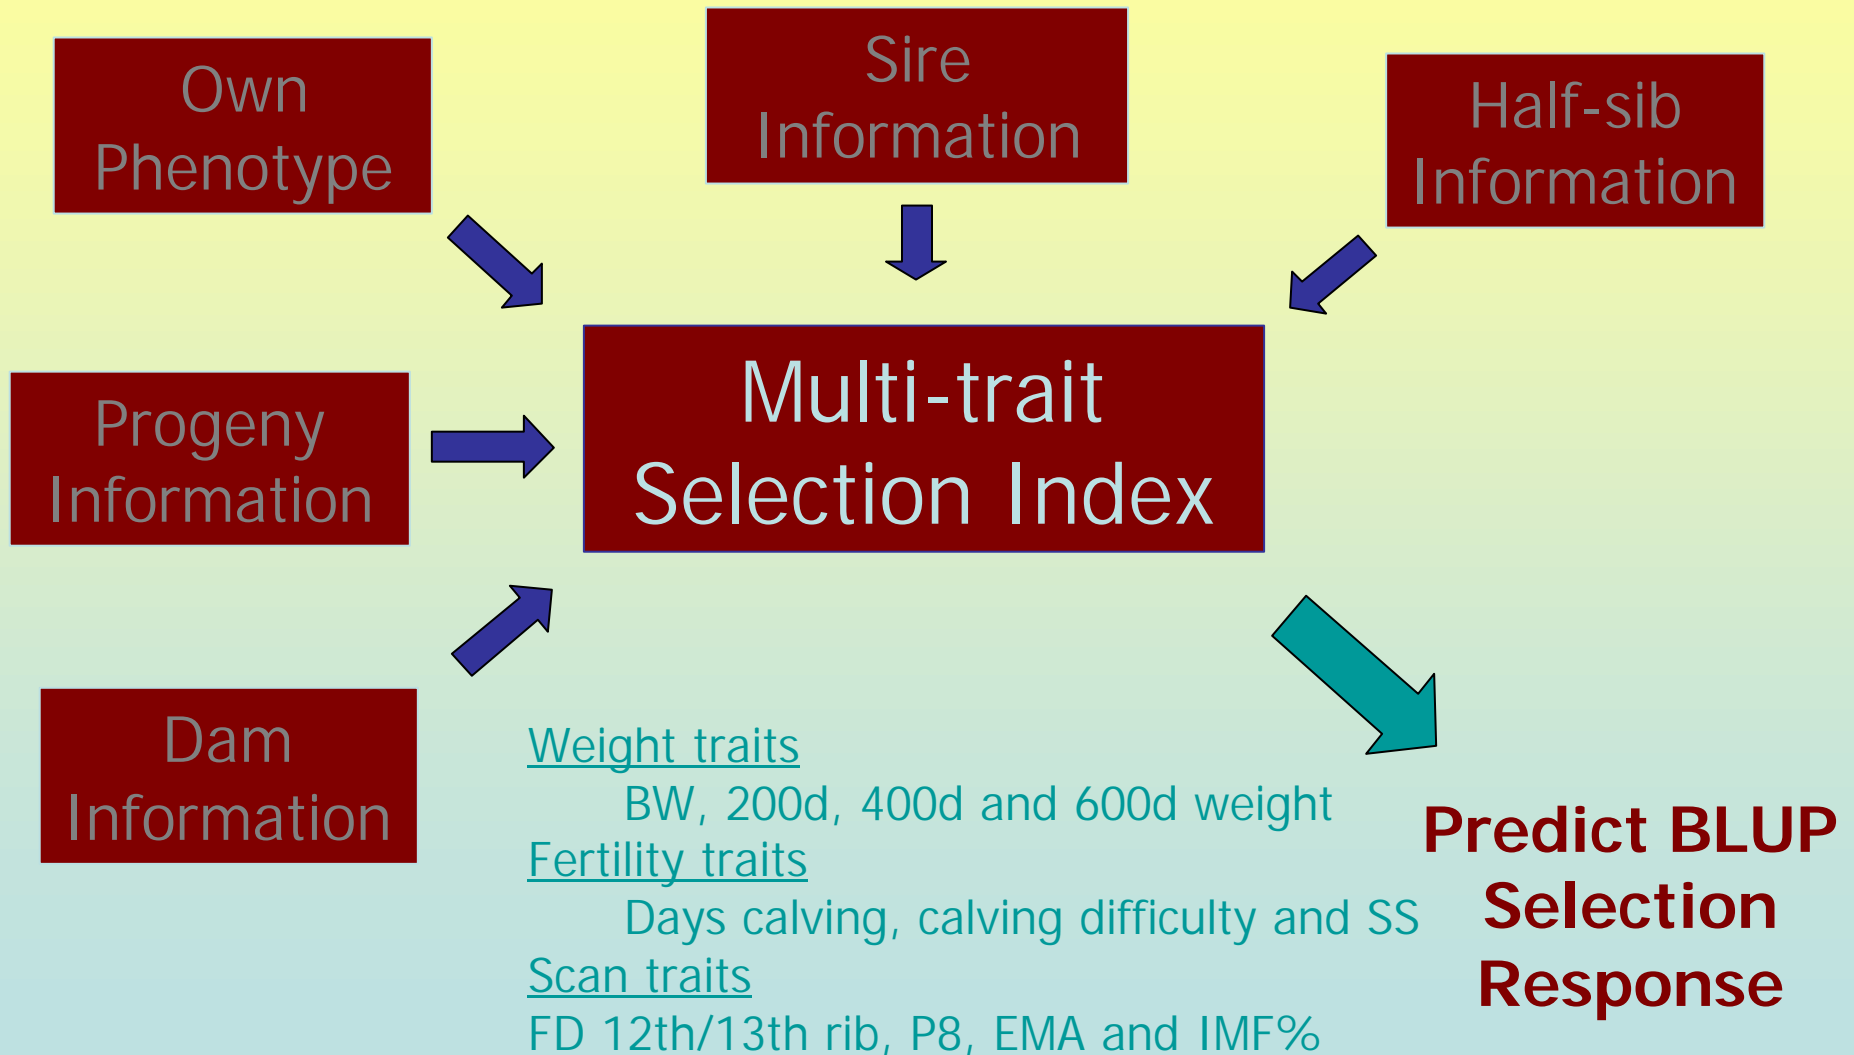

# Genotype Notification

# Method: Pseudo-BLUP Selection Index

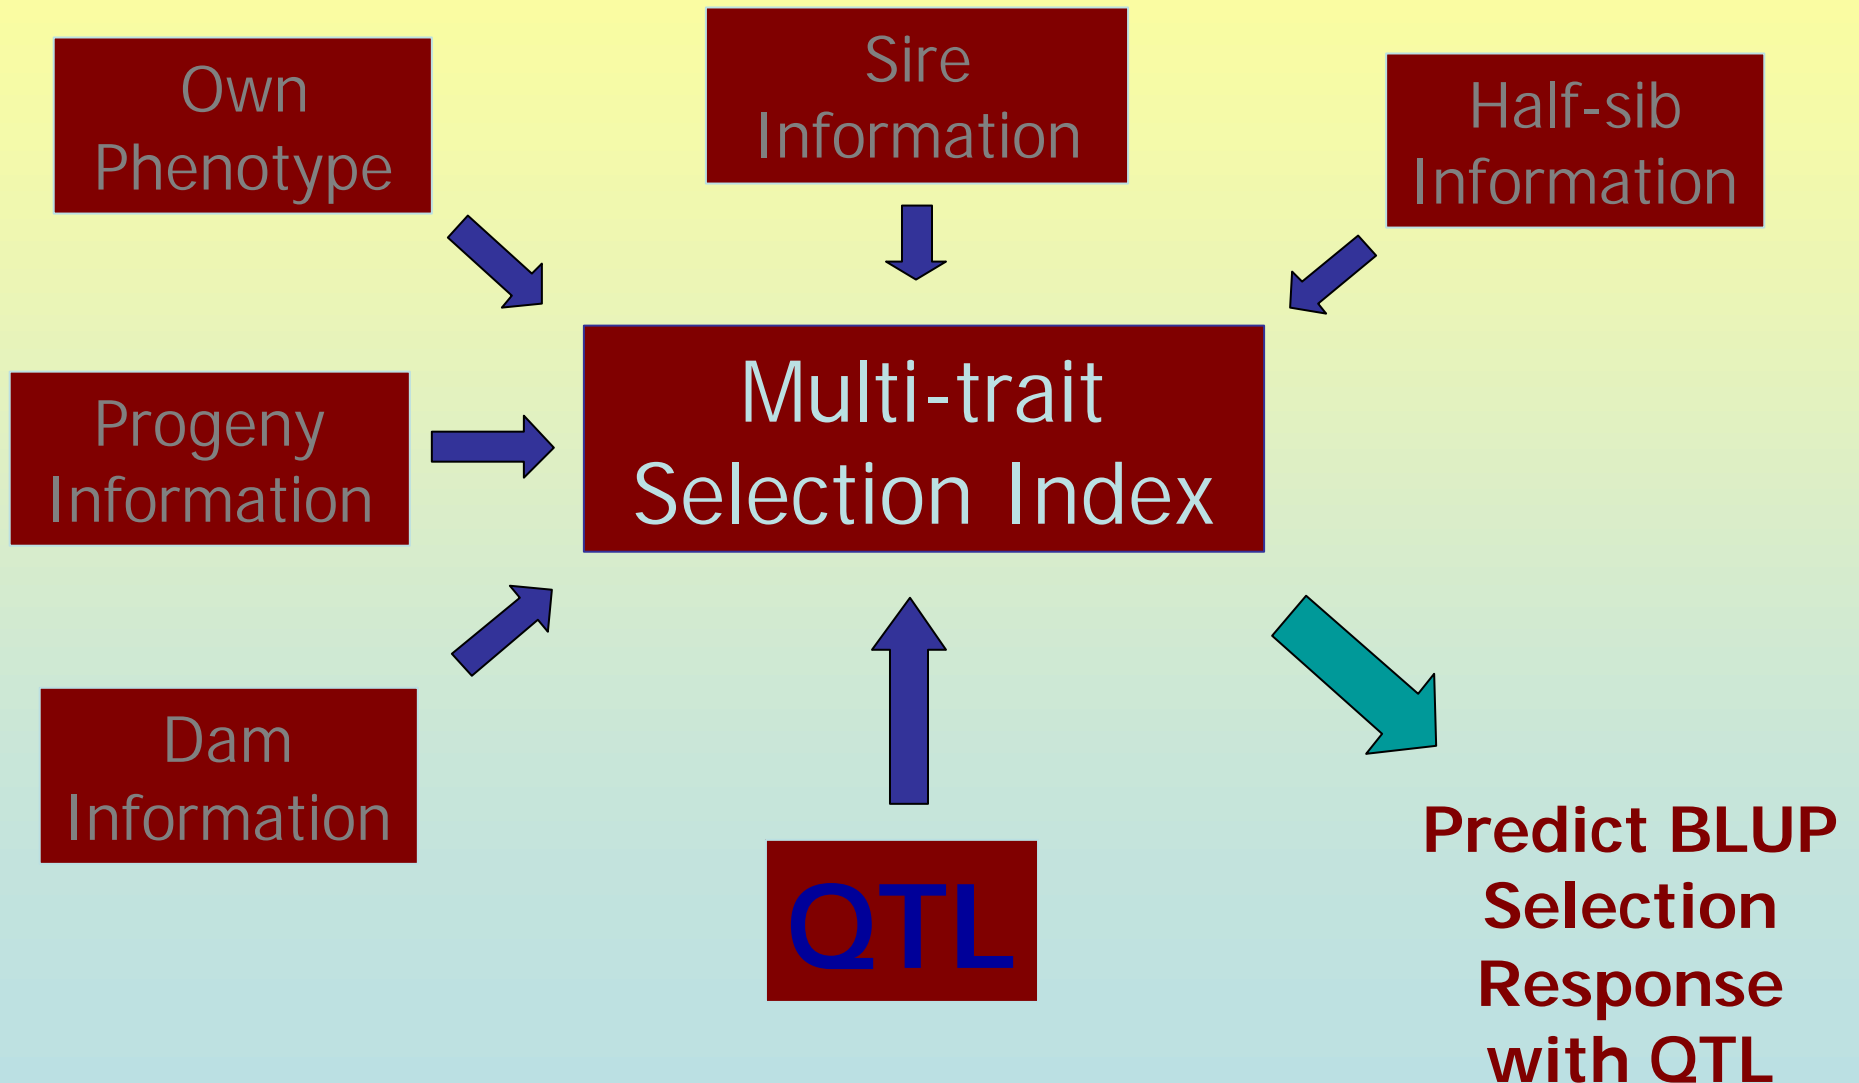

# Method: Pseudo-BLUP Selection Index

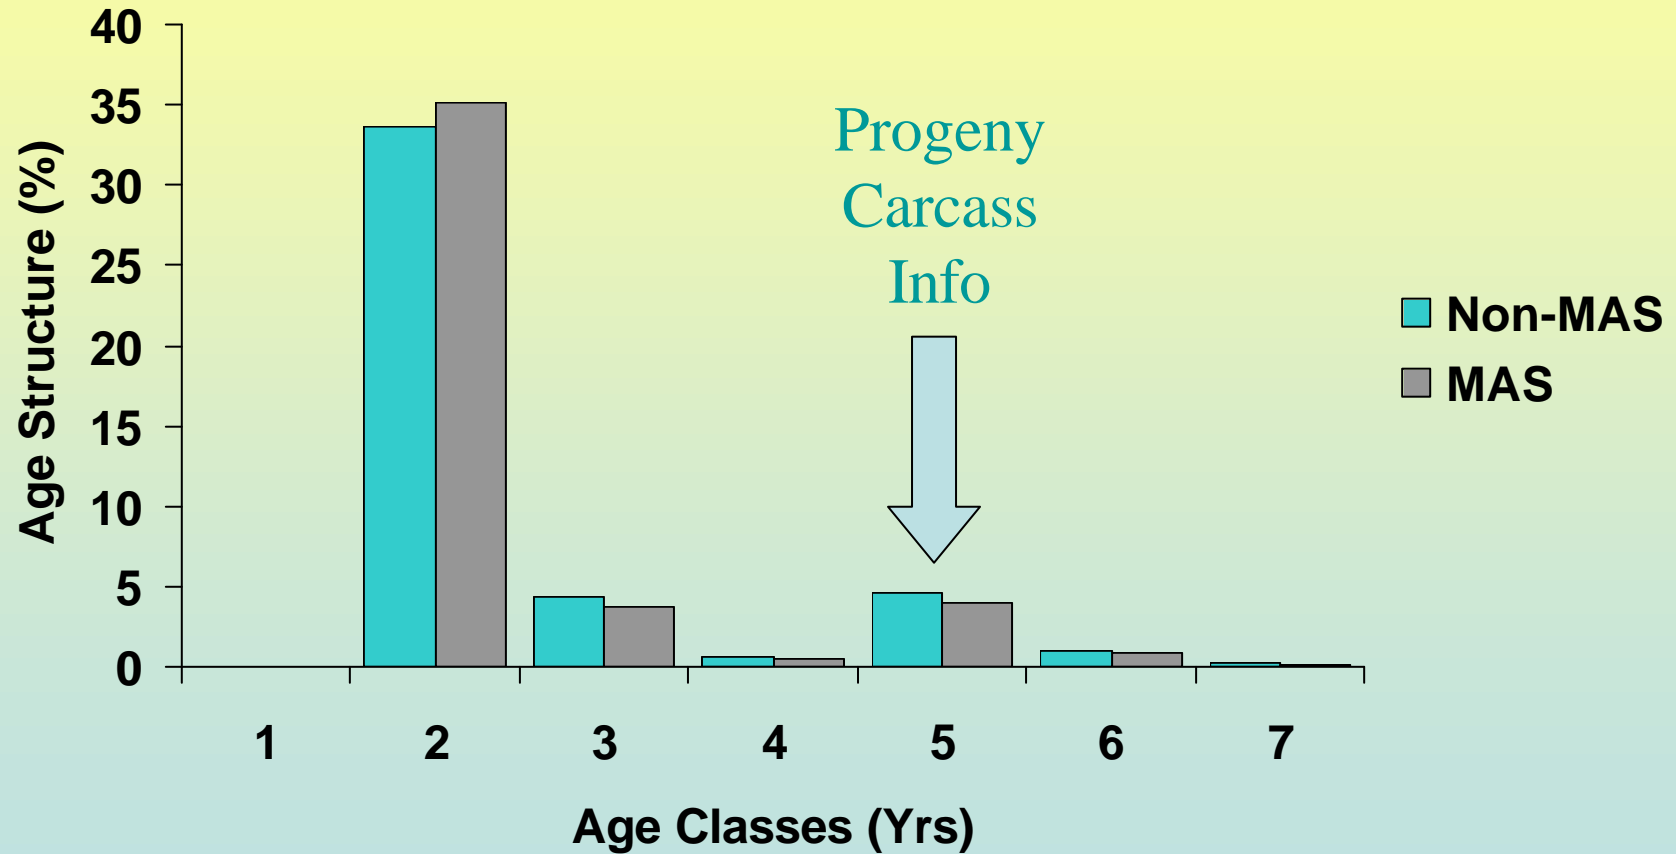

# Method: Pseudo-BLUP Selection Index

# Population Structure – Selection from 2 years

# Population Structure – Availability Year 1 = 30%

# Change in Gene Frequency

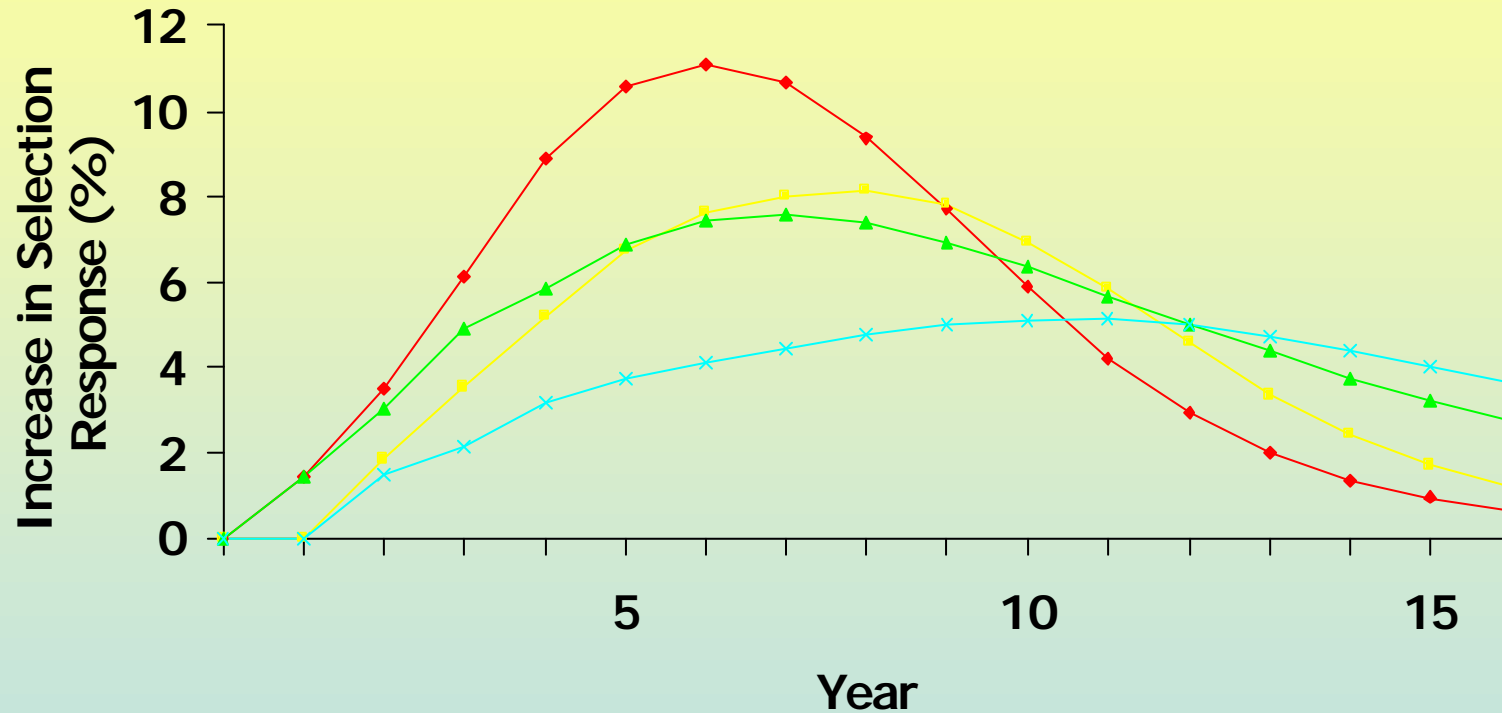

Male and Female  
Genotyping

Male Only Genotyping

Available for selection from 1 Year of Age

# Increase in Annual Selection Response – Large QTL

- ◆ Males and Females (Year 1)
- Males Only (Year 1)
- ▲ Males and Females (Year 2)
- × Males Only (Year 2)

# Take home message

- Genotyping benefits depend on:
  - Gene inheritance
  - Genotype costs
  - Size of the gene effect
- As RFI is moderately heritable QTL the value of marker is decreased considerably if early selection not used.
- Optimisation of age structure is important
